Programming interface...

Remember

MPI (Message Passing Interface) is a multi-process model whose mode of communication between the processes is **explicit**.

==> communication management is the responsibility of the user.

OpenMP (Open Multi-Processing) is a multitasking model whose mode of communication between tasks is **implicit**

==> communications is the responsibility of the compiler.

MPI (**M**essage **P**assing **I**nterface)

MPI (Message Passing Interface)

MPI is a library of subroutines (in Fortran, C, C++)

MPI allows the coordination of a program running as multiple processes in a distributed-memory environment.

MPI is flexible enough to also be used in a shared-memory environment.

MPI programs can be used and compiled on a wide variety of single platforms or (homogeneous or heterogeneous) clusters of computers over a network.

MPI library is standardized, should work (without further changes!) on any machine on which the MPI library is installed.

MPI: Basic Environment

```
MPI_Init(&argc, &argv)
```

Initializes MPI environment

Must be called in every MPI program

Must be first MPI call

Can be used to pass command line arguments to all

```
MPI_Finalize()
```

Terminates MPI environment

Last MPI function call

MPI: Basic Environment

```
MPI_Comm_rank(comm, &rank)
```

Returns the rank of the calling MPI process
Within the communicator, comm
MPI_COMM_WORLD is set during Init(...)
Other communicators can be created if needed

```
MPI_Comm_size(comm, &size)
```

Returns the total number of processes
Within the communicator, comm

```
int my_rank, size;  
MPI_Init(&argc, &argv);  
MPI_Comm_rank(MPI_COMM_WORLD, &my_rank);  
MPI_Comm_size(MPI_COMM_WORLD, &size);
```

MPI: Point-to-Point Communication

```
MPI_Send(&buf, count, datatype, dest, tag, comm)
```

Send a message

Returns only after buffer is free for reuse

Blocking

```
MPI_Recv(&buf, count, datatype, source, tag, comm, &status)
```

Received a message

Returns only when the data is available

Blocking

```
MPI_SendRecv(...)
```

Two way communication

Blocking

MPI: Point-to-Point Communication

Blocking

- Only returns after completed
 - Received: data has arrived and ready to use
 - Send: safe to reuse sent buffer
- Be aware of deadlocks
- Tip: use when possible

Non-Blocking

- returns immediately
 - Unsafe to modify buffers until operation is known to be complete
- Allows computation and communication to overlap
- Tip: Use only when needed

MPI: Deadlock

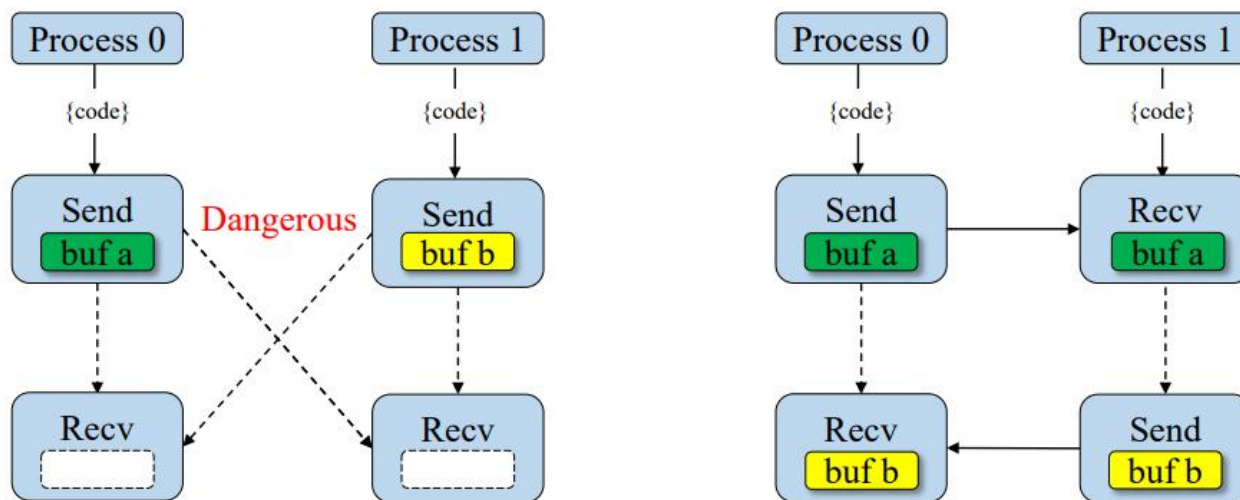

Blocking calls can results in deadlock

One process is waiting for message that will never arrive

Only option is to abort the interrupt/kill the code (CTRL-c)

Might not always deadlock - depends on size of system buffer

MPI: Coolective Communication (BCast)

```
MPI_Bcast(&buffer, count, datatype, root, comm)
```

Broadcast a message from the root process to all other processes.
Useful when reading in input parameters from file.

MPI: Collective Communication (Scatter)

```
MPI_Scatter(&sendbuf, sendcnt, sendtype, &recvbuf,  
           recvcnt, recvtype, root, comm)
```

Sends individual messages from the root process to all other processes.

MPI: Collective Communication (Gather)

```
MPI_Gather(&sendbuf, sendcnt, sendtype, &recvbuf,  
          recvnt, recvtype, root, comm)
```

Opposite of Scatter.

MPI: Collective Communication (Reduce)

```
MPI_Reduce(&sendbuf, &recvbuf, count, datatype,  
           mpi_operation, root, comm)
```

Applies **reduction** operation on data from **all processes**.

Puts results on root process.

Operator
MPI_SUM
MPI_MAX
MPI_MIN
MPI_PROD

MPI: Collective Communication (Allreduce)

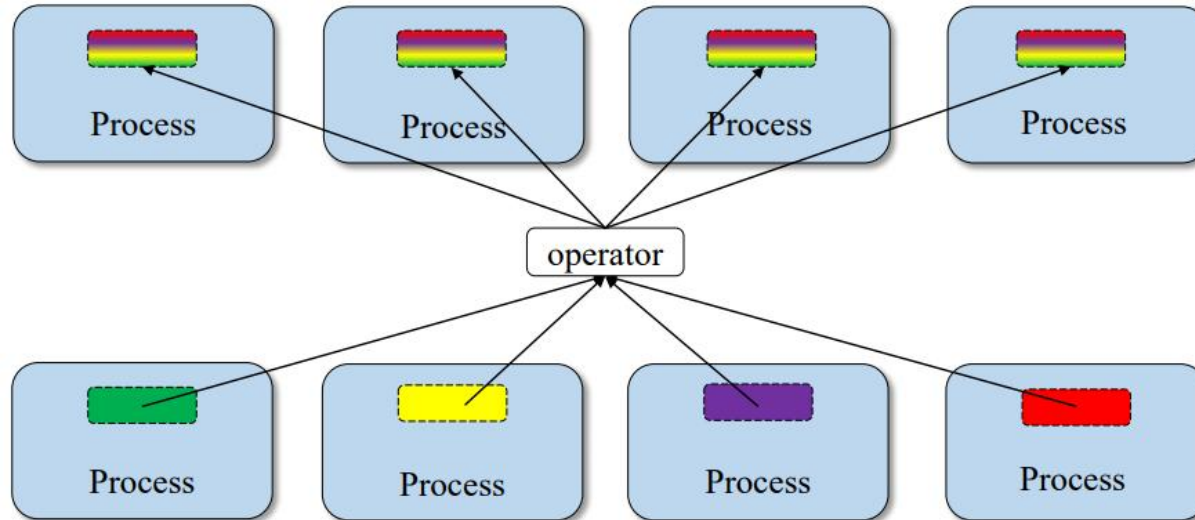

```
MPI_Allreduce(&sendbuf, &recvbuf, count,  
             datatype, mpi_operation, comm)
```

Applies **reduction** operation on data **from all processes**.

Store results on all processes.

Operator
MPI_SUM
MPI_MAX
MPI_MIN
MPI_PROD

MPI: Collective Communication (Barrier)

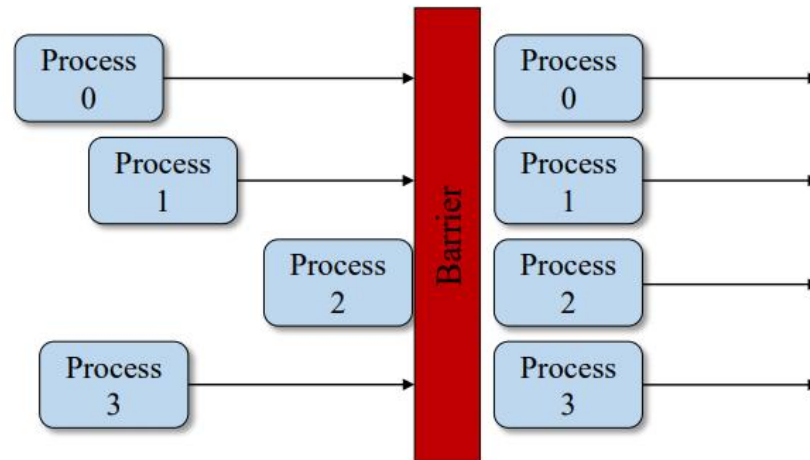

```
MPI_Barrier(comm)
```

Process synchronization (blocking).

All processes forced to wait for each other.

Use only where necessary.

Will reduce parallelism.

MPI: keywords

1 environment

- MPI Init: Initialization of the MPI environment
- MPI Comm rank: Rank of the process
- MPI Comm size: Number of processes
- MPI Finalize: Deactivation of the MPI environment
- MPI Abort: Stopping of an MPI program
- MPI Wtime: Time taking

2 Point-to-point communications

- MPI Send: Send message
- MPI Isend: Non-blocking message sending
- MPI Recv: Message received
- MPI Irecv: Non-blocking message reception
- MPI Sendrecv and MPI Sendrecv replace: Sending and receiving messages
- MPI Wait: Waiting for the end of a non-blocking communication
- MPI Wait all: Wait for the end of all non-blocking communications

3 Collective communications

- MPI Bcast: General broadcast
- MPI Scatter: Selective spread
- MPI Gather and MPI Allgather: Collecting
- MPI Alltoall: Collection and distribution
- MPI Reduce and MPI Allreduce: Reduction
- MPI Barrier: Global synchronization

4 Derived Types

- MPI Contiguous type: Contiguous types
- MPI Type vector and MPI Type create hvector: Types with a constant
- MPI Type indexed: Variable pitch types
- MPI Type create subarray: Sub-array types
- MPI Type create struct: H and erogenous types
- MPI Type commit: Type commit
- MPI Type get extent: Recover the extent
- MPI Type create resized: Change of scope
- MPI Type size: Size of a type
- MPI Type free: Release of a type

MPI: Keywords

5 Communicator

- MPI Comm split: Partitioning of a communicator
- MPI Dims create: Distribution of processes
- MPI Cart create: Creation of a Cartesian topology
- MPI Cart rank: Rank of a process in the Cartesian topology
- MPI Cart coordinates: Coordinates of a process in the Cartesian topology
- MPI Cart shift: Rank of the neighbors in the Cartesian topology
- MPI Comm free: Release of a communicator

6 MPI-IO

- MPI File open: Opening a file
- MPI File set view: Changing the view
- MPI File close: Closing a file

6.1 Explicit addresses

- MPI File read at: Reading
- MPI File read at all: Collective reading
- MPI File write at: Writing

6.2 Individual pointers

- MPI File read: Reading
- MPI File read all: collective reading
- MPI File write: Writing
- MPI File write all: collective writing
- MPI File seek: Pointer positioning

6.3 Shared pointers

- MPI File read shared: Read
- MPI File read ordered: Collective reading
- MPI File seek shared: Pointer positioning

7.0 Symbolic constants

- MPI COMM WORLD, MPI SUCCESS
- MPI STATUS IGNORE, MPI PROC NULL
- MPI INTEGER, MPI REAL, MPI DOUBLE PRECISION
- MPI ORDER FORTRAN, MPI ORDER C
- MPI MODE CREATE, MPI MODE ONLY, MPI MODE EXIST, MPI MODE EXIST ONLY

MPI: Program Basics

Include MPI Header File

Start of Program
(Non-interacting Code)

Initialize MPI

Run Parallel Code &
Pass Messages

End MPI Environment

(Non-interacting Code)

End of Program

```
#include <mpi.h>
```

```
int main (int argc, char *argv[])  
{
```

```
    MPI_Init(&argc, &argv);
```

```
    .  
    .    // Run parallel code  
    .
```

```
    MPI_Finalize(); // End MPI Envir
```

```
    return 0;  
}
```

MPI: Example

```
#include <mpi.h>
#include <stdio.h>

int main (int argc, char *argv[]) {

    int rank, size;

    MPI_Init (&argc, &argv); //initialize MPI library

    MPI_Comm_size(MPI_COMM_WORLD, &size); //get number of processes
    MPI_Comm_rank(MPI_COMM_WORLD, &rank); //get my process id

    //do something
    printf ("Hello World from rank %d\n", rank);
    if (rank == 0) printf("MPI World size = %d processes\n", size);

    MPI_Finalize(); //MPI cleanup

    return 0;
}
```

- 4 processes

```
Hello World from rank 3
Hello World from rank 0
MPI World size = 4 processes
Hello World from rank 2
Hello World from rank 1
```

- Code ran on each process independently
- MPI Processes have *private* variables
- Processes can be on completely different machines

MPI: Example Broadcast

```
#include<iostream>
#include<mpi.h>
using namespace std;
int main (int argc, char *argv[])
{
    int numprocs,myid,namelen;
    char processor_name[MPI_MAX_PROCESSOR_NAME];
    MPI_Init(&argc,&argv);
    MPI_Comm_size(MPI_COMM_WORLD,&numprocs);
    MPI_Comm_rank(MPI_COMM_WORLD,&myid);
    MPI_Get_processor_name(processor_name,&namelen);

    double reel=(double) myid;
    cout<<"Before " <<myid<<" of "<<numprocs<<" on "<<processor_name<<" integervalue "<<reel<<endl;

    MPI_Bcast(&reel,1, MPI_DOUBLE,3,MPI_COMM_WORLD);
    MPI_Barrier( MPI_COMM_WORLD);

    cout<<"After " <<myid<<" of "<<numprocs<<" on "<<processor_name<<" integervalue "<<reel<<endl;

    MPI_Finalize();
    exit(0);
}
```

*Broadcast a message from the root process to all other processes.
Useful when reading in input parameters from file.*

MPI: Example Point-to-Point communication

```
#include<iostream>
#include<mpi.h>
using namespace std;
int main (int argc, char *argv[])
{
    int numprocs,myid;
    MPI_Init(&argc,&argv);

    MPI_Comm_size(MPI_COMM_WORLD,&numprocs);
    MPI_Comm_rank(MPI_COMM_WORLD,&myid);

    MPI_Status status;
    int small=myid;
    cout<<"Before " <<myid<<" of "<<numprocs<<" small = "<<small,<<endl;

    If (myid==0) { MPI_Send(&small,1,MPI_INT,3,10,MPI_COMM_WORLD); }

    If (myid==3) { MPI_Recv(&small,1,MPI_INT,0,10,MPI_COMM_WORLD,&status) }

    MPI_Barrier( MPI_COMM_WORLD);

    cout<<"After " <<myid<<" of "<<numprocs<<" small = "<<small<<endl;

    MPI_Finalize();
}
```

MPI: Example Reduction

```
...
#include<mpi.h>
using namespace std;
double f( double a ) {return (4.0 / (1.0 + a*a));}
int main( int argc, char *argv[])
{
    int myid, numprocs;
    MPI_Init(&argc,&argv);
    MPI_Comm_size(MPI_COMM_WORLD,&numprocs);
    MPI_Comm_rank(MPI_COMM_WORLD,&myid);
    int n = 1000000000;
    double pi,sum=0.0;
    double startwtime = 0.0;
    if (myid == 0) { startwtime = MPI_Wtime(); }
    MPI_Bcast(&n, 1, MPI_INT, 0, MPI_COMM_WORLD);
    for (int i = myid + 1; i <= n; i += numprocs) { sum += f((i-0.5)/(double) n); }
    sum/= (double) n;
    MPI_Reduce(&sum, &pi, 1, MPI_DOUBLE, MPI_SUM, 0, MPI_COMM_WORLD);
    if (myid == 0)
    {
        cout<<"pi is approximately equal "<<setprecision(16) << pi <<" Error is"<<fabs(pi - M_PI)<<endl;
        cout<<"Wall clock time = "<<MPI_Wtime()-startwtime<<endl;
    }
    MPI_Finalize();
    Exit(0);
}
```

GOAL : The following code computes the π number by using a numerical evaluation of an integral by a rectangle method.

Each virtual core computes a part of the loop and a reduction instruction is performed

COMPILING an MPI Program

- **Compiling a program** for MPI is almost just like compiling a regular C or C++ program
 - The C compiler is **mpicc** and the C++ compiler is **mpic++**.
 - For example, to compile **MyProg.c** you would use a command like
 - **mpicc -O2 -o MyProg MyProg . c**

OpenMP (**O**pen **M**ulti-**P**rocessing)

OpenMP

OpenMP (Open Multi-Processing)

OpenMP is a programming interface for parallel computing on shared memory architecture.

- **It allows you to manage:**

- the creation of light processes
- the sharing of work between these lightweight processes
- synchronizations (explicit or implicit) between all light processes
- the status of the variables (private or shared).

OpenMP (Open Multi-Processing)

- **Shared memory model**

- Threads communicate by accessing shared variables

- **The sharing is defined syntactically**

- Any variable that is seen by two or more threads is shared
- Any variable that is seen by one thread only is private

- **Race conditions possible**

- Use synchronization to protect from conflicts
- Change how data is stored to minimize the synchronization

OpenMP (Open Multi-Processing)

- **Multicore CPUs are everywhere:**

- Servers with over 100 cores today and more
- Even smartphone CPUs have 8 cores

- **Multithreading, natural programming model**

- All processors share the same memory
- Threads in a process see same address space
- Many shared-memory algorithms developed

- **Multithreading is hard**

- Lots of expertise necessary
- Deadlocks and race conditions
- **Non-deterministic** behavior makes it hard to debug

OpenMP: Terminology and behavior

- **OpenMP Team** = Master + Worker
- **Parallel Region** is a block of code executed by all threads simultaneously (**has implicit barrier**)
 - The master thread always has thread id 0
 - Parallel regions can be nested
 - If clause can be used to guard the parallel region

OpenMP: Constructs

Parallel region

Thread creates team, and becomes master (id 0)

All threads run code after

Barrier at end of parallel section

```
#pragma omp parallel [clause ...]
    if (scalar_expression)
    private (list)
    shared (list)
    default (shared | none)
    firstprivate (list)
    lastprivate (list)
    reduction (operator: list)
    num_threads (integer)
```

structured_block

(not a complete list)

OpenMP Parallel Clauses

```
#pragma omp parallel if (scalar_expression)
```

Only execute in parallel.
Otherwise serial.

```
#pragma omp parallel private (list)
```

Data local to thread.
Value are **not guaranteed to be defined on exit** (even if defined before)
No storage associated with original object
Use firstprivate and/or lastprivate clause to override

```
#pragma omp parallel firstprivate (list)
```

Variables in list are private.
Initialized with the value the variable had before entering the construct.

```
#pragma omp parallel for lastprivate (list)
```

Only in for loops
Variables in list are private.
The thread that executes the sequentially last iteration updates the value of the variables in the list.

OpenMP Parallel Clauses

```
#pragma omp shared (list)
```

Data is accessible by all threads in team.
All threads access same address space.

Improperly scoped variables are big source of OMP bugs

- Shared when should be private
- Race condition

```
#pragma omp default (shared | none)
```

Tip: Safest is to use default (none) and declare by hand.

OpenMP Barrier

When a thread reaches a barrier it only continues after all the threads in the same thread team have reached it

Each barrier must be encountered by all threads in a team, or none at all

The sequence of work-sharing regions and barrier regions encountered must be same for all threads in team

Implicit barrier at the end of: do, parallel, single, workshare

OpenMP: Caution Race Condition

When multiple threads simultaneously read/write
Multiple OMP solutions

- Reduction
- Atomic
- Critical

```
#pragma omp parallel for private(i) shared(sum)
for (i=0; i<N; i++) {
    sum += i;
}
```

Should be 3!

OpenMP: Critical Section

One solution: use critical
Only one thread at a time can execute a
critical section

```
#pragma omp critical
{
    sum += i;
}
```

Downside ?
SLOOOOWWW
Overhead and serialization

OpenMP: Atomic

Atoms like "mini" critical
Only one line
Certain limitations

```
#pragma omp atomic  
sum += i;
```

Hardware controlled
Less overhead the critical

OpenMP Reduction

```
#pragma omp reduction (operator:variable)
```

Avoids race condition

Reduce variable must be shared

Makes variable private, then performs operator at end of loop

operator cannot be overloaded (c++)

One of: +, *, -, / (and &, ^, |, &&, ||)

OpenMP 3.1: added min and max for c/c++

```
#include <omp.h>
#include <stdio.h>

int main() {

    int i;
    const int N = 1000;
    int sum = 0;

    #pragma omp parallel for private(i) reduction(+: sum)
    for (i=0; i<N; i++) {
        sum += i;
    }

    printf("reduction sum=%d (expected %d)\n", sum, ((N-1)*N)/2);
}
```

OpenMP: Scheduling omp for

How does a loop get split up ?

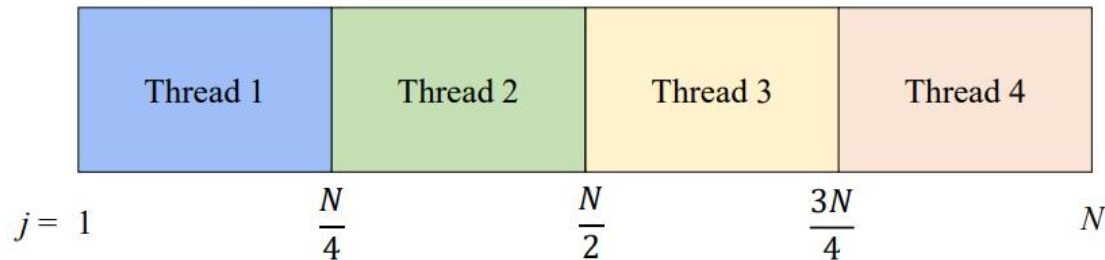

In MPI, we have to do it manually

If you do not tell what to do, the compiler decides

Usually compiler chooses "static" - chunks of N/p

```
#pragma omp parallel for default(shared) private(j)
  for (j=0; j<N; j++) {
    ... // some work here
  }
```

Unspecified schedule

OpenMP: Static Scheduling

You can tell the compiler what size chunks to take.

```
#pragma omp parallel for default(shared) private(j) schedule(static,10)
for (j=0; j<N; j++) {
    ... // some work here
}
```

Keeps assigning chunks until done.

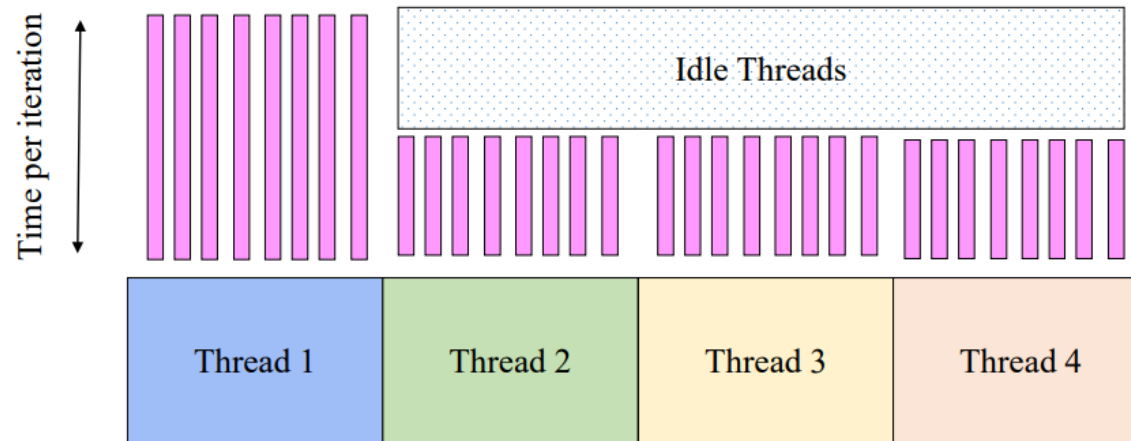

Chunk size that is not a multiple of the loop will result in thread with uneven numbers.

OpenMP: Problem with Static Scheduling

What happens if loop iterations do not take the same amount of time ?

Load imbalance

OpenMP: Dynamic Scheduling

Chunks are assigned on the fly, as threads become available
When a thread finishes on chunk, it is assigned another

```
#pragma omp parallel for default(shared) private(j) schedule(dynamic,10)
  for (j=0; j<N; j++) {
    ... // some work here
  }
```

Caveat: higher overhead than static!

OpenMP omp for Scheduling Recap

```
#pragma omp parallel for schedule(type [,size])
```

Scheduling types

Static

- Chunks of specified size assigned round-robin

Dynamic

- Chunks of specified size are assigned when thread finishes previous chunk

Guided

- Like dynamic, but chunks are exponentially decreasing
- Chunk will not be smaller than specified size

Runtime

- Type and chunk determined at runtime via environment variables

OpenMP: API

- API for library calls that perform useful functions
- Must include "omp:h"
- Will not compile without OpenMP compiler support

```
#include <omp.h> //<-- necessary header file for OpenMP API
#include <stdio.h>

int main(int argc, char *argv[]){

    printf("OpenMP running with %d threads\n", omp_get_max_threads());

    #pragma omp parallel
    {
        //Code here will be executed by all threads
        printf("Hello World from thread %d\n", omp_get_thread_num());
    }

    return 0;
}
```

OpenMP: API

```
void omp_set_num_threads(int num_threads)
```

Sets number of threads used in next parallel section
Overrides OMP_NUM_THREADS environment variable
Positive integer

```
int omp_get_max_threads()
```

Returns max possible (generally set by OMP_NUM_THREADS)

```
int omp_get_num_threads()
```

Returns number of threads currently in team

```
int omp_get_thread_num()
```

Returns thread id of calling thread
Between 0 and omp_get_num_threads-1

```
double omp_get_wtime()
```

Returns number of seconds since some point
Use in pairs time=(t2-t1)

OpenMP: Example

```
#include <stdio.h>

int main(int argc, char* argv[])
{
    printf("Hello world! -main\n");
    #pragma omp parallel
    {
        printf(".. worker reporting for duty.\n");
    }
    printf("Over and out! -main\n");
}
```

```
> gcc -fopenmp omp_hello.c -o omp
> OMP_NUM_THREADS=3 ./omp
Hello world! -main
.. worker reporting for duty.
.. worker reporting for duty.
.. worker reporting for duty.
Over and out! -main
```

```
void cholesky(int ts, int nt, double* a[nt][nt]) {
    for (int k = 0; k < nt; k++) {
        // Diagonal Block factorization
        #pragma omp task depend(inout: a[k][k])
        potrf(a[k][k], ts, ts);

        // Triangular systems
        for (int i = k + 1; i < nt; i++) {
            #pragma omp task depend(in: a[k][k])
                        depend(inout: a[k][i])
            trsm(a[k][k], a[k][i], ts, ts);
        }

        // Update trailing matrix
        for (int i = k + 1; i < nt; i++) {
            for (int j = k + 1; j < i; j++) {
                #pragma omp task depend(inout: a[j][i])
                                depend(in: a[k][i], a[k][j])
                dgemm(a[k][i], a[k][j], a[j][i], ts, ts);
            }
            #pragma omp task depend(inout: a[i][i])
                        depend(in: a[k][i])
            syrk(a[k][i], a[i][i], ts, ts);
        }
    }
}
```

OpenMP 4.0

OpenMP: Example Gauss-Seidel

```
void gauss_seidel(int tsteps, int size, int TS, int (*p)[size]) {
    int NB = size / TS;

    #pragma omp parallel
    #pragma omp single
    for (int t = 0; t < tsteps; ++t)
        for (int ii=1; ii < size-1; ii+=TS)
            for (int jj=1; jj < size-1; jj+=TS) {
                #pragma omp task depend(inout: p[ii:TS][jj:TS])
                depend(in: p[ii-TS:TS][jj:TS], p[ii+TS:TS][jj:TS],
                      p[ii:TS][jj-TS:TS], p[ii:TS][jj+TS:TS])
                {
                    for (int i=ii; i<(1+ii)*TS; ++i)
                        for (int j=jj; j<(1+jj)*TS; ++j)
                            p[i][j] = 0.25 * (p[i][j-1] * p[i][j+1] *
                                                p[i-1][j] * p[i+1][j]);
                }
            }
}
```

Gauss-Seidel Method is used to solve the linear system Equations. It is a method of iteration for solving n linear equation $Ax=b$ with the unknown variables.

OpenMP: Summary

OpenMP: Performance Tips

- Avoid serialization!
- Avoid using `#pragma omp parallel for` before each loop
 - Can have significant overhead
 - Thread creation and scheduling is NOT free!!
 - Try for broader parallelism
 - One `#pragma omp parallel`, multiple `#pragma omp for`
 - Always try to parallelize the outer most loop
- Use reduction whenever possible
- Minimize I/O
- Minimize `critical`
 - Use `atomic` instead of `critical` where possible

Hybrid OpenMP-MPI

Hybrid MPI and OpenMP

Hybrid application programs using **MPI + OpenMP** are now common place on large HPC systems.

There are basically two main motivations:

1. Reduced memory footprint, both in the application and in the MPI library (eg communication buffers).
2. Improved performance, especially at high core counts where pure MPI scalability runs out.

Hybrid MPI and OpenMP

Parallel programming models

Parallel execution is based on threads or processes (or both) which run at the same time on different CPU cores

Processes

- Interaction is based on exchanging messages between processes
- MPI (Message passing interface)

Threads

- Interaction is based on shared memory, i.e. each thread can access directly other threads data
- OpenMP

Hybrid MPI and OpenMP

1: MPI: Processes

- Independent execution units
- Have their own memory space
- MPI launches N processes at application startup
- Works over multiple nodes

Supercomputer node

2: OpenMP: Threads

- Threads share memory space
- Threads are created and destroyed (parallel regions)
- Limited to a single node

3: Hybrid programming: Launch threads (OpenMP) within processes (MPI)

- Shared memory programming inside a node, message passing between nodes
- Optimum MPI task per node ratio depends on the application and should always be experimented.

Hybrid Programming

In hybrid programming each process can have **multiple threads executing simultaneously**
All threads within a process share all MPI objects Communicators, requests, etc.

MPI defines 4 levels of thread safety:

- **MPI_THREAD_SINGLE** : One thread exists in program
- **MPI_THREAD_FUNNELED** : Multithreaded but only the master thread can make MPI calls Master is one that calls `MPI_Init_thread()`
- **MPI_THREAD_SERIALIZED**: Multithreaded, but only one thread can make MPI calls at a time
- **MPI_THREAD_MULTIPLE**: Multithreaded and any thread can make MPI calls at any time. Use `MPI_Init_thread` instead of `MPI_Init` if more than single thread

Hybrid Programming

Potential advantages of the hybrid approach

- Fewer MPI processes for a given amount of cores
 - Improved load balance
 - All-to-all communication bottlenecks alleviated
- Decreased memory consumption if an implementation uses replicated data
- Additional parallelization levels may be available
- Possibility for dedicating threads for different tasks
 - e.g. dedicated communication thread or parallel I/O
- Dynamic parallelization patterns often easier to implement with OpenMP

Disadvantages of hybridization

- Increased overhead from thread creation/destruction
- More complicated programming
 - Code readability and maintainability issues
- Thread support in MPI and other libraries needs to be considered

Hybrid Programming: Example

```
#include <mpi.h>
#include <omp.h>

int main(int argc, char *argv[]) {
    int my_id, omp_rank;
    int provided, required=MPI_THREAD_FUNNELED;

    MPI_Init_thread(&argc, &argv, required,
                    &provided);
    MPI_Comm_rank(MPI_COMM_WORLD, &my_id);
    #pragma omp parallel private(omp_rank)
    {
        omp_rank = omp_get_thread_num();
        printf("I'm thread %d in process %d\n",
              omp_rank, my_id);
    }
    MPI_Finalize();
}
```

```
$ mpicc -fopenmp hybrid-hello.c -o hybrid-hello
$ srun --ntasks=2 --cpus-per-task=4
  ./hybrid-hello
```

```
I'm thread 0 in process 0
I'm thread 0 in process 1
I'm thread 2 in process 1
I'm thread 3 in process 1
I'm thread 1 in process 1
I'm thread 3 in process 0
I'm thread 1 in process 0
I'm thread 2 in process 0
```

Hybrid Programming Example

- Numerical integration

$$\int_0^1 \frac{4}{1+x^2} dx = \pi$$

- Discretization:

$$\Delta = 1/N: \text{step} = 1/\text{NBIN}$$

$$x_i = (i+0.5)\Delta \quad (i = 0, \dots, N-1)$$

$$\sum_{i=0}^{N-1} \frac{4}{1+x_i^2} \Delta \cong \pi$$

```
#include <stdio.h>
#define NBIN 100000
void main() {
    int i; double step,x,sum=0.0,pi;
    step = 1.0/NBIN;
    for (i=0; i<NBIN; i++) {
        x = (i+0.5)*step;
        sum += 4.0/(1.0+x*x);}
    pi = sum*step;
    printf("PI = %f\n",pi);
}
```

```
#include <stdio.h>
#include <stdlib.h>
#include <mpi.h>          /* MPI header file */
#include <omp.h>           /* OpenMP header file */
#define NUM_STEPS 100000000
#define MAX_THREADS 4

int main(int argc, char *argv[]) {
    int nprocs, myid;
    int tid, nthreads, nbin;
    double start_time, end_time;
    double pi, Psum=0.0, sum[MAX_THREADS]={0.0};
    double step = 1.0/(double) NUM_STEPS;

    /* initialize for MPI */
    MPI_Init(&argc, &argv); /* starts MPI */
    /* get number of processes */
    MPI_Comm_size(MPI_COMM_WORLD, &nprocs);
    /* get this process's number (ranges from 0 to nprocs - 1) */
    MPI_Comm_rank(MPI_COMM_WORLD, &myid);

    nbin= NUM_STEPS/nprocs;
```

Hybrid Programming Example

```
#pragma omp parallel private(tid)
{
    int i;
    double x;
    nthreads=omp_get_num_threads();
    tid=omp_get_thread_num();
    for (i=nbin*myid+tid; i < nbin*(myid+1); i+= nthreads) { /* changed */
        x = (i+0.5)*step;
        sum[tid] += 4.0/(1.0+x*x);
    }
}
for(tid=0; tid<nthreads; tid++) /*sum by each mpi process*/
    Psum += sum[tid]*step;

MPI_Reduce(&Psum, &pi, 1, MPI_DOUBLE, MPI_SUM, 0, MPI_COMM_WORLD);/* added */

if (myid == 0) {
    printf("parallel program results with %d processes:\n", nprocs);
    printf("pi = %g (%17.15f)\n", pi, pi);
}
MPI_Finalize();

return 0;
}
```

Results

- **MPI**
MPI uses 8 processes:
pi = 3.14159 (3.141592653589828)
- **OpenMP**
OpenMP uses 8 threads:
pi = 3.14159 (3.141592653589882)
- **Hybrid**
mpi process 0 uses 4 threads
mpi process 1 uses 4 threads
mpi process 1 sum is 1.287 (1.287002217586605)
mpi process 0 sum is 1.85459 (1.854590436003132)
Total MPI processes are 2
pi = 3.14159 (3.141592653589738)

Thank you for your attention !
